SWIFTTICKET

A simpler ticketing screen for bus conductors

Product design concept · Jagrit Chaudhry

The idea is simple: help conductors issue a ticket quickly, with fewer taps and less time looking at the screen.

THE PROBLEM

The assignment describes a conductor using a bulky thermal-printer device with worn buttons and a hard-to-read screen. On a moving bus, the conductor may also be handling cash, dealing with bright sunlight and serving passengers quickly.

The design goal is to make the most common task easy to see and complete: choose a destination, set the passenger count, check the fare and issue the ticket.

THE MAIN SCREEN

The destination, passenger count, fare and Issue Ticket button stay together on one screen. Recent routes are shown as shortcuts, so familiar journeys take less effort. The fare is large and easy to spot before the ticket is issued.

Key choices

• Start at one passenger each time, so a previous group’s count is not carried over by mistake.

• Keep recent destinations visible instead of hiding them behind a swipe.

• Keep the main action near the bottom of the screen for one-thumb use.

• Show a clear confirmation after issuing a ticket, with options to view or handle the ticket.

HOW IT WORKS

1. Choose destination Tap a recent route or choose another destination.	**2. Set passengers** Use + or –. The fare updates straight away.
3. Check fare Destination, passenger count and total stay visible.	**4. Issue ticket** A confirmation screen shows the route, count, fare and ticket ID.

DESIGNED FOR REAL BUS CONDITIONS

The screen uses large labels, strong contrast and generous tap areas. Important actions sit in the lower-middle part of the screen, where they are easier to reach with a thumb. The layout should be checked with both left- and right-handed conductors.

The design also avoids relying on colour alone: success and errors use words and icons. In a real product, vibration could provide extra feedback, but the screen would still show the result.

IF SOMETHING GOES WRONG

Wrong destination	Show the chosen destination before issue. If a ticket has already been issued, offer a controlled void flow where operator rules allow it.
Printer problem	Keep the ticket details on screen and offer retry or a digital display if the operator permits it.
Weak connection	Show whether a transaction is waiting to sync. Offline ticketing would need approved rules from the operator.
Reprint	Let the conductor find a recent ticket and re-display or reprint it without creating a second ticket.

NAVIGATION & REACH

The main ticket screen gets the most space. Recent tickets and Shift Summary are secondary screens. Printing appears after a ticket is issued, instead of taking up space on the main screen.

For one-handed use, the main controls stay in the lower-middle area. Less-used options sit farther away from the thumb. Critical actions do not depend on gestures.

WHAT THE CLICKABLE DEMO COVERS

• Choose a sample destination and change passenger count.

• See the fare update and issue a sample ticket.

• Review recent sample tickets and a shift summary.

• Try the example offline, re-display and void interactions.

The prototype uses sample routes and fares. It is a design demonstration, not a live ticketing service.

NEXT STEPS

• Ask conductors to try the flow while standing and while holding cash.

• Time familiar and unfamiliar routes, and record missed taps or wrong selections.

• Check screen readability in direct sunlight and test with both hands.

• Confirm fare, concession, offline, printing and cancellation rules with the transport operator.

SwiftTicket is a proposed concept based on the assignment brief. It is not an official BMTC/BEST product.
